

RISK INTELLIGENCE FOR ROBINHOOD CHAIN STOCK TOKENS

Robinhood Chain Stock Tokens trade on-chain. What they are meant to represent does not. **Parity exists to watch the distance between the two.**

"Is this Stock Token still trading at parity with what it is supposed to represent?"

MINI-MANIFESTO · V1

01 THE PROBLEM

Robinhood Chain Stock Tokens create an on-chain market for assets whose value is meant to track something else — a **reference price**, observed elsewhere, updated on its own schedule. The two do not have to move in lockstep. An on-chain price can drift above its reference (a **premium**) or below it (a **discount**), and the distance between them is a Stock Token's **deviation from parity**.

Seeing that a deviation exists is easy — read two numbers, subtract. Understanding what the deviation *means* is harder. A small premium that appears and disappears within an hour is not the same condition as a discount that persists for a day. A deviation that is unremarkable for one Stock Token may be extreme for another. A single percentage, on its own, carries no history and no context.

WHAT PARITY WATCHES

This is the line Parity watches: the point of exact correspondence between what a Stock Token is trading for on-chain and what it is meant to represent. Everything Parity reports is a statement about distance from that line — and about what that distance has looked like over time.

02 THE INTELLIGENCE LAYER

Parity continuously observes verified on-chain and reference data for each supported Stock Token and accumulates a historical record. From that record it builds a **baseline**: a historical median for the token’s own deviation, and a baseline dispersion — measured as a **MAD (median absolute deviation)** — describing how much that deviation has varied around its median. Today’s reading is then measured against that baseline as a **MAD multiple**: how far the current deviation sits from the historical median, relative to the baseline dispersion.

Read that scale for what it says and no more: a statement about how far today’s reading sits from this Stock Token’s own recent history — not a verdict, not a prediction, and not an instruction.

MATURITY

A baseline needs enough observations and enough elapsed time before it is trusted to mean anything. A young Stock Token is honestly reported as still developing, never forced into a premature verdict.

PERSISTENCE

A momentary blip and a sustained **episode** are genuinely different conditions. Parity tracks how long an abnormal reading has held, not just that it occurred once.

03 PRINCIPLES

01 Independent

Parity is not affiliated with Robinhood. It observes public, verifiable data and reports what it finds.

02 Read-only

Parity does not execute trades, custody assets, or take any action on a user's behalf. It is an instrument, not an intermediary.

03 Data-honest

When a reading is unavailable — a stale reference, a paused oracle, an upstream source that failed to respond — Parity reports it as unavailable. Never silently zero. Never quietly guessed.

04 Not advice

A classification of SEVERE is not a sell signal. A classification of NORMAL is not a buy signal. Parity's thresholds are current operating hypotheses about relative abnormality, not validated boundaries of risk.

WHAT COMES NEXT

Robinhood Chain Stock Token markets are early. As they grow, the questions worth asking about them will grow too — not only *is this trading at parity*, but *how deep is this market, and under what conditions can it actually be traded*. Parity has already begun preserving the raw on-chain observations — pool liquidity, reserve balances, tick and price state — that this next layer of questions will eventually depend on. That work today is deliberately limited to honest collection, not interpretation: no execution score exists yet, and no claim is made that a raw balance is the same thing as tradeable depth.
